The database is in a shared network location (not stored in an isolated partition). We no longer have the key for the encryption. We also have backups of the DB. Is it possible to restore the DB on a new server? If yes, is there a way to retrieve the encryption key from the backup and still use it to restore the database? A: If you have not yet opened it, you can just try to use Imported data wizard to import the data as well as the Encryption. It will ask you to specify a username and password And then specify the same here as well It will give you option to select the database After which it will ask you for the file containing the encrypted columns Just browse and select the file. Then it will ask you for the encryption keys It will prompt you for one if you are doing in-place encryption If you are performing out-of-place encryption it will prompt for a new key and then ask for it. You can use any of these keys to decrypt the data. Q: Value type vs Reference type difference I want to get the difference between value type and reference type. I mean value type is of data type which is stored on the memory. And reference type is of object type which is stored on the memory. Is this correct? A: Value types are fixed in size, while reference types can be as large or small as you like. The main difference between reference types and value types is that value types are allocated on the stack while reference types are allocated on the heap. If an object is on the heap, you can modify it. If it is on the stack, you cannot modify it, it is basically a copy of the data type and you cannot change its values. A: You can say that a value type is a type that can be treated as a value on its own. If you allocate a value type the data in it will be on the stack and not referenced anywhere else. A reference type is a type that allows you to reference objects outside of the current scope. A:
